Carbon dioxide pollution expected to rise about 1%, new record in 2023

Global emissions of planet-heating carbon dioxide are expected to rise around 1% to reach a new all-time high in 2023. The carbon pollution will need to be cut almost in half this decade to meet the world's targets of limiting global warming and avoiding catastrophic climate impacts. Global CO₂ emissions should be falling by around 5% this year, instead of it, the year will see emissions up between 0.5% and 1.55.
